One of the major deficiencies of population studies carried out in Tunisia are the lack of information about genetic polymorphism of major genes and the usage of genetic markers in population genetics. This study aimed to evaluate the usefulness of DNA fingerprinting and RAPD-PCR techniques as an approach to fingerprinting human populations in Tunisia and to apply it to the quality control of the G6PD deficiency screening method. The methods have been applied to seven samples of human populations from different regions of Tunisia, including Ksar-el-Biar city. DNA fingerprints and PCR amplifications using three primers (OPI-07, OPI-17 and OPI-19) produced reproducible and consistent results. Both methods were performed to characterize genetic polymorphism between the polymorphic patterns of the seven populations. Our results indicate a high level of polymorphism in the populations we studied. The OPI-07 primer was the most effective of the three, and gave seven alleles, of which five were polymorphic. They included three alleles of the BFS Caucasian type and two new alleles, one from Northern Africa and one from the sub-Sahara. The most polymorphic loci, OPI-17 and OPI-19, were linked at 0.7 centimorgans (cM) of distal markers. Based on these results, we propose the use of DNA fingerprinting and RAPD-PCR techniques in the quality control of G6PD deficiency screening method. The results indicate that a modified procedure of the micromethod test to eliminate false negative specimens and to confirm positive results can be implemented without any significant reduction of sensitivity.Cementless and cement-retained total hip arthroplasty: indications, outcome, and analysis of factors affecting longevity. A total of 516 Travatan Modular stems (Zimmer, Warsaw, Ind) were inserted in 501 patients between October 2003 and June 2010. We analysed our results in 516 hips, and factors influencing the functional outcome and the longevity of the prostheses. All of
